Medical College of Wisconsin

September 17, 2025

Single-arm phase II trial

Harun, Sparapani et al. 2025 Head & Neck

- ► Head and Neck Squamous Cell Carcinoma (HNSCC) is the sixth most common cancer worldwide
- ► Treating locally recurrent HNSCC is challenging resulting in high morbidity and poor outcomes
- ► The standard of care for patients is salvage surgery
- ▶ But surgery achieves durable control in <50% of patients
- ► Immune checkpoint blockade with PD-1 inhibitors has been approved by the US FDA
- ► PD-1 inhibitors have a favorable toxicity profile
- ► Enrolled a single-arm after 6 months of adjuvant nivolumab following surgery
- ► A historical control group with surgery alone was identified from electronic medical records for comparison
- ▶ 39 treated patients and 66 controls satisfied our study criteria
- ▶ disease-free survival (DFS): time from salvage resection to the first evidence of a tumor or all-cause mortality

Rubin's causal model: Potential outcomes framework

Rubin 1974 Journal of Educational Psychology Neyman 1923 Annals of Agricultural Sciences

- Suppose we have a dichotomous treatment $Z_i = 1$ is treated vs. $Z_i = 0$ is control
- ightharpoonup The potential outcome is denoted $Y_i(Z)$, but only one is observed
- ▶ $Y_i(Z_i)$ is the observed *actual/factual* outcome while $Y_i(1 Z_i)$ is the unobserved *counter-factual*
- $Y_i = Z_i Y_i(1) + (1 Z_i) Y_i(0)$

Rubin's causal model: Potential outcomes framework

- i. *Stable unit treatment value assumption* (SUTVA). The potential outcome of any patient is unaffected by any other; also known as the assumption of no interference.
- ii. *Consistency*. The values of the intervention are well-defined such that a patient's potential outcome under the observed treatment corresponds to their observed outcome.
- iii. Conditional exchangeability. The conditional probability of receiving a given treatment depends only on the observed baseline covariates, X_i , that we denote $(Y_i(0), Y_i(1)) \perp Z_i | X_i$.
- iv. *Positivity*. There is a positive probability of receiving treatment given the covariates: $P[Z_i = 1|X_i] > 0$.

Survival analysis and potential outcomes

- \blacktriangleright Here we are interested in time to DFS denoted by Y_i
- ► The maximum length of follow-up in this study is L = 36 months
- ▶ And some patients were censored earlier: $C_i \le 36$
- ightharpoonup Therefore, we cannot observe Y_i for everyone
- We can only ascertain $T_i = \delta_i Y_i + (1 \delta_i) C_i$ where $\delta_i = \mathbf{I}(Y_i < C_i)$ is the event indicator
- Nevertheless, our interest is for the survival probability: $S(t) = P[Y_i > t]$.
- ▶ Define a success (failure) as 1 (0) for no DFS (DFS) at time t by the dichotomous temporal process $A_i(t, Z_i) = I(Y_i(Z_i) > t)$ where $P[A_i(t, Z_i) = 1 | X_i, Z_i] = S(t | X_i, Z_i)$
- This process is random yielding 1 at each success time t: $(t \le T_i, \delta_i = 0)$ or $(t < T_i, \delta_i = 1)$
- ▶ Then deterministically 0 at/after failure time: $(t \ge T_i, \delta_i = 1)$

Survival analysis and potential outcomes: Consistency

- ► However, our process $A_i(t, Z_i)$ has to abide by causal *Consistency* (Assumption ii.)
- ▶ The potential outcome due to the treatment actually assigned, Z_i , must correspond to the observed outcome.

For the factual outcome process, $A_i(t, Z_i)$, we have two cases

- Observed $\delta_i = 1$: the process yields successes (1) for times $t \in (0, T_i)$ and failures (0) for times $t \in [T_i, L]$
- Censored $\delta_i = 0$: the process yields successes (1) for times $t \in (0, T_i]$ while unobserved for times $t \in (T_i, L]$

Survival analysis and potential outcomes: the individual treatment effect

► The *individual treatment effect* (ITE) is defined as follows

If
$$\delta_i = 1$$
 or $(\delta_i = 0, t \le T_i)$, then $ITE_i(t) = Z_i(A_i(t, 1) - S(t|X_i, 0)) + (1 - Z_i)(S(t|X_i, 1) - A_i(t, 0))$
Else: $ITE_i(t) = S(t|X_i, 1) - S(t|X_i, 0)$

- \blacktriangleright However, notice that each ITE_i naturally depends on X_i
- ightharpoonup Rather, we want the *marginal* that is free of X_i
- ► Frequentist methods rely on *G-computation* for inference
- ► These *marginal structural models* employ linear regression
- ► Linearity is a precarious restrictive assumption we want to avoid
- ▶ Of course, Bayesians have an elegant solution: the *value function*
- ► Very similar to Friedman's partial dependence function

Qian & Murphy 2011 *Annals of Statistics* Logan, Sparapani, et al. 2019 *SMMR*

Survival analysis and potential outcomes: the value function and the average treatment effect

Harun, Sparapani et al. 2025 Head & Neck

- We chose discrete time BART to estimate $S(t|X_i, Z_i)$
- ► The value function marginal at the *m*th MCMC draw $N^{-1} \sum_i \text{ITE}_{im}(t)$ is now free of X_i
- Leading directly to the average treatment effect $\widehat{ATE}(t) = N^{-1}M^{-1}\sum_{m}\sum_{i} ITE_{im}(t)$
- And its corresponding 1α level credible interval $(\sum_i \text{ITE}_{im_{\alpha/2}}(t), \sum_i \text{ITE}_{im_{1-\alpha/2}}(t))$
- ► Our R programs are included in the **BART3** package
- ► R> system.file("HNSCC", package = "BART3")
- ► And the data too: R> ?hnscc

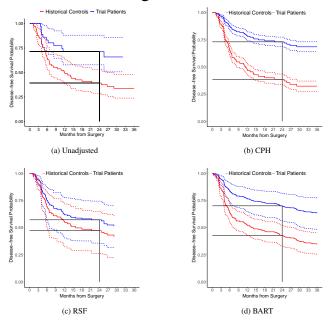

Baseline Characteristics

	Single		Hist	torical
	Arm		Co	ntrols
Total	39			66
Age:mean(SD)	66	(9)	61	(11)
Male	27	69%	43	65%
Caucasian	34	87%	59	89%
10+ pack-years	24	62%	51	77%
5+ drinks/week	8	21%	24	36%
Prior chemotherapy	22	56%	39	59%

2011-19 vs. 2002-10				

Pocock's Acceptability Criteria of Historical Controls

Pocock's Criteria (paraphrased for brevity on this slide)	Met?
Must have received a precisely defined standard treatment	Yes
the same as the treatment for the randomized controls.	
2. The group must have been part of a recent clinical study	Yes
which contained the same requirements for patient eligibility.	
3. The methods of treatment evaluation must be the same.	Yes
4. The distributions of important patient characteristics	Mostly yes
in the group should be comparable with those in the new trial.	
5. The previous study must have been performed in the	Mostly yes
same organization with largely the same clinical investigators.	
6. There must be no other indications to expect differing	Uncertain
results between the randomized and historical controls.	

Disease-Free Survival Marginal Effects and ATE

Estimates of 2-year Disease-Free Survival

DFS	Single Arm			Historical Controls		
Unadjusted	0.714	(0.578,	0.881)	0.392	(0.289,	0.533)
CPH	0.731	(0.688,	0.775)	0.387	(0.337,	0.436)
RSF	0.571	(0.357,	0.744)	0.472	(0.262,	0.651)
BART*	0.701	(0.595,	0.807)	0.432	(0.340,	0.535)
